

Figure 2.1 A modern computer system.

For a computer to start running—for instance, when it is powered up or rebooted—it needs to have an initial program to run. This initial program, or *bootstrap program*, tends to be simple. It initializes all aspects of the system, from CPU registers to device controllers to memory contents. The bootstrap program must know how to load the operating system and to start executing that system. To accomplish this goal, the bootstrap program must locate and load into memory the operating-system kernel. The operating system then starts executing the first process, such as “init,” and waits for some event to occur. The occurrence of an event is usually signaled by an *interrupt* from either the hardware or the software. Hardware may trigger an interrupt at any time by sending a signal to the CPU, usually by way of the system bus. Software may trigger an interrupt by executing a special operation called a *system call* (also called a *monitor call*).

There are many different types of events that may trigger an interrupt—for example, the completion of an I/O operation, division by zero, invalid memory access, and a request for some operating-system service. For each such interrupt, a service routine is provided that is responsible for dealing with the interrupt.

When the CPU is interrupted, it stops what it is doing and immediately transfers execution to a fixed location. The fixed location usually contains the starting address where the service routine for the interrupt is located.
