REACTIONS

REACTION COORDINATE DIAGRAM

Plot of energy vs. reaction progress

- Activation energy (E_a):** Energy barrier that reactants must overcome in order to react; energy difference between the reactants and the transition state.
- Transition state:** Arrangement of atoms that represents the highest energy point along the path from reactants to products; exists for an extremely short time.
- Intermediate population:** The transition state in a reaction will more closely resemble whichever species (reactants or products) it is closest to in energy.
- Reactive intermediates:** Chemical species that exists in a potential energy well along the path from reactants to products, but is less stable and is more stable than a transition state.

INCREASING REACTION RATES

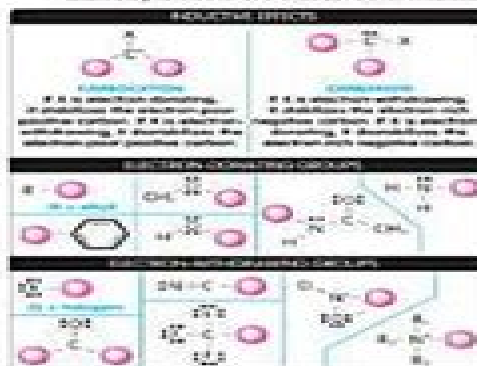

- Catalysts:** Substances that increase the rate of a reaction by lowering activation energy, but are not consumed in the reaction; catalyze lower activation energy either by stabilizing the transition state or destabilizing reactants.
- Solvent:** The solvent in which a reaction takes place can increase the rate of a reaction either by stabilizing the transition state or by stabilizing the reactants.
- Hydrogen bonding:** Hydrogen bonding hydrogen atoms not bonded to carbon can participate in reactions by donating protons.
- Aprotic solvents:** Solvents that do not contain hydrogen atoms or that contain hydrogen atoms bonded to carbon.
 - Polar solvents stabilize charged and polar molecules.
 - Nonpolar solvents stabilize nonpolar molecules.

POLAR AND NONPOLAR SOLVENTS	
APROTIC SOLVENTS	PROTIC SOLVENTS
<chem>CH3-C(=O)-CH3</chem> Acetone (Aprotic) <chem>CH3-C(=O)-CH2-CH3</chem> Ethyl methyl ketone (Aprotic) <chem>CH3-O-CH3</chem> Dimethyl ether (Aprotic) <chem>c1ccccc1</chem> Benzene (Aprotic)	<chem>H2O</chem> Water (Protic) <chem>CH3-C(=O)-OH</chem> Acetic acid (Protic) <chem>CH3-CH2-OH</chem> Ethanol (Protic) <chem>CH3-C(=O)-CH2-CH2-OH</chem> 4-Hydroxybutan-2-one (Protic) <chem>CH3-C(=O)-CH2-CH3</chem> Butan-2-one (Protic)

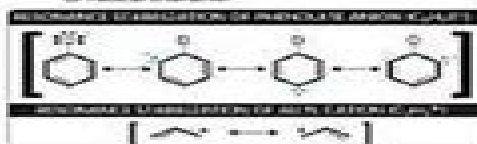

- Temperature:** Reaction rates increase with increasing temperature, as additional heat energy can be used to carry reactants over the activation energy barrier.
- Light:** Light can be used to initiate radical reactions, as it can induce homolytic cleavage of covalent bonds.

TYPES OF REACTIONS

- Concerted reaction:** Reactants are converted to products through a single transition state.
- Stepwise reaction:** Reactants are converted to products through one or more steps, which involve one or more reactive intermediates.
- Stabilization of reactive intermediates:**
 - Inductive effects:** Alkyl and functional groups within a molecule can "donate" or "withdraw" electron density through σ bonds to compensate for changes caused by formation of the reactive intermediate.

- Resonance:** Intermediates that have resonance forms are stabilized by the delocalization of charge or radical character.

- Types of reactive intermediates in organic chemistry:
 - Carbocation:** Electron-deficient species containing a positively charged carbon atom with three substituents for a total of six valence electrons; carbocations have trigonal planar geometry and are electrophilic.
 - Radical:** Electron-deficient species in which an atom has an unpaired electron.
 - Factors affecting carbocation and carbon radical stability:**
 - Substitution:** Alkyl substituents donate electron density and delocalize positive charge or electron deficiency to stabilize carbocations and carbon radicals, in terms of carbocation stability, tertiary > secondary > primary > methyl.
 - Resonance:** Alkenes, carbocations, and carbon radicals by delocalizing positive charge or electron deficiency over a larger area.
 - Carbocation:** Chemical species containing a negatively charged carbon atom with three substituents plus an unpaired electron pair for a total of eight valence electrons; carbocations are nucleophilic.
 - Factors affecting carbocation stability:**
 - Hybridization:** Because electrons are closer to the nucleus in s orbitals than in p orbitals, stabilization of carbocations increases as the s character of the orbital holding the unpaired electron increases, in terms of carbocation stability, $sp > sp^2 > sp^3$.
 - Resonance:** Carbocations are stabilized by delocalizing positive charge over a larger area.

REACTION MECHANISMS

- Reaction:** The reaction bonds are broken and formed during the course of a reaction; reaction mechanisms show movement of electrons and formation of intermediates by which reactants are converted to products.
- Curved arrow notation:** Use of curved arrows to indicate the flow of electrons in a reaction mechanism; full-headed arrows denote movement of an electron pair, half-headed arrows denote movement of a single electron.
 - Movement of electrons is accompanied by the movement of any atoms or groups associated with those electrons.
- Heterolytic cleavage:** Breaking of a covalent bond in which both bonding electrons become associated with one of the atoms involved in the bond.
- Heterogeneous Bond Heterolysis:** A formation of a covalent bond in which both bonding electrons are donated by one of the atoms or the bond.
 - Nucleophile:** Chemical species that is electron-rich and can donate an electron lone pair to a carbocation or heterogenic bond formation.
 - Any species carrying an electron lone pair can act as a nucleophile.
 - The nucleophilicity of a species depends on a number of factors, but it follows some general trends:
 - There is some correlation between the basicity of a species and its nucleophilicity.
 - Nucleophilicity increases moving down a group in the periodic table (e.g., I^- is more nucleophilic than Cl^- and Br^- is more nucleophilic than OH^-).

- Electrophile:** Chemical species that is electron-poor and can accept an electron lone pair from a nucleophile to heterogenic bond formation.
- Polar reactions:** Reactions whose mechanisms involve heterolytic cleavage and heterogenic bond formation.
- Heterolytic cleavage:** Breaking of a covalent bond in which both atoms involved in the bond receive one bonding electron.
- Heterogenic bond formation:** Formation of a covalent bond in which both bonding electrons move to one of the atoms.
- Nonpolar reactions:** Reactions whose mechanisms involve homolytic cleavage and/or homogenic bond formation.
