Abstract

We extend the Burch and Dill flushing technique [6] for formal verification of microprocessors to be applicable to designs where the functional units and memories have multicycle and possibly arbitrary latency. We also show ways to incorporate exceptions and branch prediction by exploiting the properties of the logic of Positive Equality with Uninterpreted Functions [4][5]. We study the modeling of the above features in different versions of dual-issue superscalar processors.

1 Introduction

In order for formal methods to scale for verification of modern microprocessors, they need to be applicable easily and with a high degree of automation to designs with multicycle functional units, multicycle memories, exceptions, and branch prediction. Burch and Dill's verification methodology has the potential to be highly automatic, but has previously been applied only to designs with single-cycle functional units and memories that produce their results instantaneously [5][6][7][21]. The approach is very elegant in using *flushing* of the processor—feeding it with bubbles until all instructions in flight complete their execution—in order to compute an abstraction function mapping Implementation states to a Specification state. (The difference between a bubble and a nop is that a bubble does not modify any user-visible state, while a nop increments the PC.) The correctness criterion is a commutative diagram, stating that an application of the transition function of the Implementation followed by flushing should produce the same user-visible state as first flushing the Implementation and then using the resultant user-visible state to apply the transition function of the Specification between 0 and k times, where k is the issue-width of the Implementation. As observed and exploited by Burch in his controlled flushing [7], we can change the logic during flushing, since the only purpose of that logic is to compute an abstraction function. Having an improper abstraction function will not compromise the verification and can only result in a false negative.

The same correctness criterion has been adopted by the theorem-proving community and applied to an out-of-order design with exceptions and interrupts by Sawada and Hunt [17] and to an out-of-order design with only arithmetic instructions by

Hosabettu, Srivas and Gopalakrishnan [13]. However, the former approach requires the user to manually build an intermediate abstraction of the processor and to define a large number of lemmas (Sawada defined nearly 4,000, necessary for the correctness proof). The latter approach requires the user to manually define a set of completion functions, one per unfinished instruction in flight, describing how that instruction will be completed, given that all the instructions that it has data dependencies on have already been completed. Furthermore, the user has to manually define a way to compose these completion functions in order to form the abstraction function for the processor. Both of these theorem-proving methods require months of manual work for complex designs, i.e., they are not automatic.

Not only has the Burch and Dill flushing technique not been applied to processors with multicycle functional units, but Hosabettu, Srivas and Gopalakrishnan [12] have claimed that it has the drawback of being hard to use for pipelines with indeterminate latency, particularly where an ALU computation might have a data-dependent duration or a memory hierarchy of multiple levels might have a non-deterministic delay.

In this work we extend Burch and Dill's flushing-based methodology to be applicable to microprocessors with functional units and memories of multicycle and possibly arbitrary latency. We also model exceptions and branch prediction. Our most complex designs have 10 abstract instruction types. They have two completely functional pipelines, each consisting of five stages, for a total of up to 10 instructions in flight. Therefore, exhaustive binary simulation must consider 10^{10} instruction sequences of 10 instructions each. Furthermore, accounting for possible data dependencies, raised exceptions, correctness/incorrectness of the branch predictions, and multicycle computations will make that number significantly higher. Even directed simulation will probably find it very hard, if at all possible, to generate all interesting instruction sequences for such a design. However, we were able to formally verify it in less than 44 minutes of CPU time.

2 Background

The key to our success is a very efficient decision procedure [21] for the logic of Equality with Uninterpreted Functions and Memories (EUFM) [6], which exploits the properties of Positive Equality [4][5] and the c_e encoding [10] to generate a propositional formula, which is then evaluated with BDDs [3] or SAT-checkers. We found BDDs to be unmatched by SAT-checkers and SVC [18] (a decision procedure for the logic of EUFM that does not exploit Positive Equality) when verifying correct designs. However, SAT-checkers outperform BDDs on buggy processors.

The syntax of EUFM [6] includes terms and formulas. A term can be an Uninterpreted Function (UF) applied on a list of argument terms, a domain variable, or an *ITE* operator selecting between two argument terms based on a controlling formula, such that *ITE(formula, term1, term2)* will evaluate to *term1* when *formula* = **true** and to *term2* when *formula* = **false**. A formula can be an Uninterpreted Predicate (UP) applied on a list of argu-
