

## Types of Chemical Reactions

Do atoms rearrange in predictable patterns during chemical reactions?

### Why?

Recognizing patterns allows us to predict future behavior. Weather experts use patterns to predict dangerous storms so people can get their families to safety. Political analysts use patterns to predict election outcomes. Similarly, chemists classify chemical equations according to their patterns to help predict products of unknown but similar chemical reactions.

**Understanding Chemical Reactions Through the Theoretical Lenses** Wasut Pornpatcharapong,2018 Understanding a proper reaction coordinate and the free energy profile of any chemical reaction provide valuable information in elucidating the kinetics and thermodynamics properties as well as the underlying reaction mechanisms Nevertheless identifying a proper

reaction coordinate for a specific chemical reaction or computing the free energy landscape are difficult. Hence any methods that could systematically provide insights into both issues would play important roles in studies of any kind of chemical reactions. On the reaction coordinate's front, Markov State Model (MSM) is a tool that can be used to identify the reaction coordinate of the slowest motion in a simulation. Instead of the deterministic view of the MD simulations, MSM takes a probabilistic view that a configuration has a probability to evolve to another configuration after time  $t$  defined by a transfer operator which allows us to identify each motion in the system in terms of the information encapsulated in each of the operator's corresponding eigenfunctions and eigenvalues. The eigenfunctions of the transfer operator can then be projected onto the collective variable space and minimal representation of each eigenfunction in the collective variable space could be obtained. On the free energy front, efficient multidimensional free energy landscape can be reconstructed smoothly from noisy free energy estimators through Gaussian Process Regression (GPR). In this dissertation, we proposed a rigorous GPR workflow that also ensures the consistency through projection of the multidimensional landscape into each individual one-dimensional surface with errors bounded by Eigenvector Method for Umbrella Sampling (EMUS). We showed that a significant efficiency gain can be obtained through our scheme. This dissertation employed both MSM and GPR to study the dynamics of cation-anion association in aqueous solutions using LiCl and NaCl as a model. With MSM, we have completely identified all significant motions in the association process and in the bulk, and we also identify important contributions to the slowest process of the dynamics. With GPR, we have achieved a smooth reconstruction of a free energy landscape of both systems using 2 collective variables and large efficiency gain relative to traditional two-dimensional windowed simulation.
